TECHNICAL PATENT DRAWINGS

System and Method for Dynamic Value Exchange Between
Digital Content Creators and Brand Entities
Through Adaptive Persona-Based Commerce

Filing Date: 09-04-2026

Inventor: Saketh Velamuri

FIGURE 1: MULTI-PLATFORM CREATOR COMMERCE SYSTEM ARCHITECTURE

FIGURE 1 DESCRIPTION: The system architecture illustrates the multi-layered approach to creator commerce. Platform data from Instagram, YouTube, TikTok, and LinkedIn are aggregated in the Data Ingestion Layer. Three parallel processing engines (Creator Profile Adapter, Value Matching Engine, and Value Assessment Engine) operate concurrently. These feed into the central Intelligent Matching Engine which performs real-time affinity scoring and ranking. Output flows through Workflow Management and Commerce Integration layers to produce Creator Deal Flows, Brand Matches, and Real-time Analytics. This architecture enables scalability and real-time processing across heterogeneous platforms.

FIGURE 2: DATA FLOW DIAGRAM - REAL-TIME PROCESSING PIPELINE

FIGURE 2 DESCRIPTION: The data flow diagram shows real-time stream processing. Multiple data sources (Creator Metrics, Brand Requests, User Actions, Market Signals) feed into a Message Queue. These streams flow through the Stream Processing Layer which performs stateful processing, windowing, and aggregation. Three parallel computation stages (Creator Profile Computation, Affinity Score Computation, Value Assessment) operate on the processed data. A Cache Lookup layer optimizes frequent queries. The output is produced in real-time and feeds into dashboards and APIs for consumption.

FIGURE 3: MULTI-DIMENSIONAL AFFINITY MATCHING VECTOR SPACE

FIGURE 3 DESCRIPTION: The affinity matching engine operates in a multi-dimensional vector space where each creator and brand requirement is represented as a vector. Three dimensions shown are: Audience Demographic Alignment (X-axis), Engagement Quality (Y-axis), and Creator Credibility (Z-axis). The distance between a creator vector and brand requirement vector in this space represents the affinity score, with smaller distances indicating better compatibility. The system continuously updates creator vectors as new data arrives and computes distances to brand requirement vectors in real-time, enabling dynamic matching and ranking.

FIGURE 4: WORKFLOW STATE MACHINE - DEAL PROGRESSION

FIGURE 4 DESCRIPTION: The workflow state machine manages complex deal progression through defined stages: DISCOVERY (initial match), NEGOTIATION (terms discussion), CONTRACTING (agreement signing), EXECUTION (content creation), VERIFICATION (live confirmation), and PAYOUT (completion). Transitions are asynchronous and triggered by events or actions. Timeout mechanisms (red dashed paths) handle delays, and rejection/error paths return to previous states or terminate. Each transition is logged immutably for audit and compliance purposes. This design enables parallel deal processing and robust error handling across multiple concurrent deals.

FIGURE 5: DYNAMIC CREATOR PERSONA ADAPTATION

FIGURE 5 DESCRIPTION: The persona adaptation system demonstrates how a single creator can be presented differently to different brands while maintaining core authenticity. A creator's invariant characteristics (authentic voice, core values, audience base, engagement style) are preserved across all adaptations. Variable attributes are emphasized or de-emphasized depending on brand requirements. For a Tech Brand, technical skills and innovation focus are highlighted. For a Fashion Brand, aesthetic sense and trend awareness are emphasized. For a Health Brand, wellness values and community engagement are showcased. This allows the same creator to achieve higher affinity scores with diverse brands without sacrificing authenticity.

FIGURE 6: HIERARCHICAL VALUE ASSESSMENT FRAMEWORK

FIGURE 6 DESCRIPTION: The value assessment framework provides a hierarchical approach to quantifying creator value. The Total Creator Valuation (TCV) is calculated from three main components: (1) Audience Quality (Engagement Rate Index, Authentic Engagement Score, Demographic Precision), (2) Content Performance (Content Resonance Index, Cross-Platform Consistency, Audience Sentiment), and (3) Creator Credibility (Verification Status, Historical Performance, Audience Trust). Each component is calculated from detailed metrics (ERI, AES, DPS, CRI, CPCS, etc.). The final dynamic valuation adjusts the base valuation using multipliers for market demand, seasonal factors, and other real-time signals, enabling data-driven pricing and value realization for creators.

FIGURE 7: MULTI-PLATFORM INTEGRATION ARCHITECTURE

FIGURE 7 DESCRIPTION: The platform integration architecture uses an abstraction layer to unify APIs from Instagram, YouTube, TikTok, LinkedIn, and future platforms. The abstraction layer handles protocol translation, authentication, data normalization, rate limiting, and error handling, shielding the core system from platform-specific implementation details. This design enables the system to extend to new platforms with minimal core changes, supporting horizontal scaling and configuration-driven development. The core system (Metric Computation, Content Orchestration, Compliance Monitoring, Analytics Engine) operates platform-agnostically, accessing all platforms through the unified interface.
